

1 **ABSTRACT**

2 The inventive methods and systems provide an approach to protecting
3 unencrypted sensitive information from being paged out to secondary storage,
4 such as a hard disk, during paging operations. In the described embodiment, a key
5 is provided and is maintained in the main memory of a virtual memory system.
6 Measures are taken to protect the key such as page-locking the key in the main
7 memory to ensure that it never gets paged out to the secondary storage. The
8 described key is a desirably large key that is randomly generated by the operating
9 system. When sensitive information is to be placed in the main memory, it is
10 encrypted with the page-locked key. The encrypted sensitive information can then
11 be paged out to secondary storage without concern about its security. When the
12 encrypted sensitive information is needed by a process or application, it is
13 retrieved from secondary storage and decrypted using the page-locked key. For
14 further protection, the sensitive information can be decrypted into a page-locked
15 page of main memory. More than one key can be used to encrypt and/or decrypt
16 the sensitive information.
